Lecture 6

OpenMP: Synchronization

- The **ordered** construct enforces the sequential order for a block.

```
#pragma omp parallel private (tmp)
#pragma omp for ordered
    for (I=0;I<N;I++){
        tmp = NEAT_STUFF(I);
#pragma ordered
        res = consum(tmp);
    }
```

Ordered Sections

- Impose an order across the iterations of a parallel loop
- Identify a portion of code within each loop iteration that must be executed in the original, sequential order of the loop iterations.
- Restrictions:

  - If a parallel loop contains an ordered directive, then the parallel loop directive itself must contain the ordered clause.

  - An iteration of a parallel loop is allowed to encounter at most one ordered section.

```
!$omp parallel do ordered
      do i = 1, n
          a(i) = … complex calculation here …

      ! Wait until the previous iteration has finished its section
!$omp ordered
          print *, a(i)
      ! Signal the completion of ordered from this iteration
!$omp end ordered
        enddo
```

OpenMP: Synchronization

- The **master** construct denotes a structured block that is only executed by the master thread. The other threads just skip it (no implied barriers or flushes).

```
#pragma omp parallel private (tmp)
{
        do_many_things();
#pragma omp master
        {    exchange_boundaries();   }
#pragma barrier
        do_many_other_things();
}
```

OpenMP: Synchronization

- The **flush** construct denotes a sequence point where a thread tries to create a consistent view of memory.

  - All memory operations (both reads and writes) defined prior to the sequence point must complete.

  - All memory operations (both reads and writes) defined after the sequence point must follow the flush.

  - Variables in registers or write buffers must be updated in memory.

- Arguments to flush specify which variables are flushed. No arguments specifies that all thread visible variables are flushed.

OpenMP:
A flush example

- This example shows how **flush** is used to implement pair-wise synchronization.

```fortran
       integer ISYNC(NUM_THREADS)
C$OMP PARALLEL DEFAULT (PRIVATE) SHARED (ISYNC)
       IAM = OMP_GET_THREAD_NUM()
       ISYNC(IAM) = 0
C$OMP BARRIER
       CALL WORK()
       ISYNC(IAM) = 1    ! I'm all done; signal this to other threads
C$OMP FLUSH(ISYNC)
       DO WHILE (ISYNC(NEIGH) .EQ. 0)
C$OMP FLUSH(ISYNC)
       END DO
C$OMP END PARALLEL
```

Make sure other threads can see my write.

Make sure the read picks up a good copy from memory.

Note – the following examples illustrate the ordering properties of the flush operation. In the following incorrect pseudocode example, the programmer intends to prevent simultaneous execution of the critical section by the two threads, but the program does not work properly because it does not enforce the proper ordering of the operations on variables **a** and **b**.

Incorrect example:

```
                        a = b = 0

   thread 1                              thread 2

   b = 1                                 a = 1
   flush (b)                             flush (a)
   flush (a)                             flush (b)
   if (a == 0) then                      if (b == 0) then
      critical section                      critical section
   end if                                end if
```

The problem with this example is that operations on variables **a** and **b** are not ordered with respect to each other.

For instance, nothing prevents the compiler from moving the flush of **b** on thread 1 or the flush of **a** on thread 2 to a position completely after the critical section (assuming that the critical section on thread 1 does not reference **b** and the critical section on thread 2 does not reference **a**).

If either re-ordering happens, the critical section can be active on both threads simultaneously.

The following correct pseudocode example correctly ensures that the critical section is executed by not more than one of the two threads at any one time. Notice that execution of the critical section by neither thread is considered correct in this example.

Correct example:

```
                              a = b = 0

    thread 1                                  thread 2

    b = 1                                     a = 1
    flush(a,b)                                flush(a,b)
    if (a == 0) then                          if (b == 0) then
        critical section                          critical section
    end if                                    end if
```

The compiler is prohibited from moving the flush at all for either thread, ensuring that the respective assignment is complete and the data is flushed before the if statement is executed.

OpenMP:
Implicit synchronization

- **Barriers are implied on the following OpenMP constructs:**

```
end parallel
end do  (except when nowait is used)
end sections (except when nowait is used)
end critical
end single (except when nowait is used)
```

- **Flush is implied on the following OpenMP constructs:**

```
barrier
critical, end critical
end do
end parallel
```

```
end sections
end single
ordered, end ordered
```

OpenMP: Some subtle details on directive nesting

- *For*, *sections* and *single* directives binding to the same parallel region can't be nested.

- Critical sections with the same name can't be nested.

- *For*, *sections*, and *single* can not appear in the dynamic extent of *critical*, *ordered* or *master*.

- *Barrier* can not appear in the dynamic extent of *for*, *ordered*, *sections*, *single*., *master* or *critical*

- *Master* can not appear in the dynamic extent of *for*, *sections* and *single*.

- *Ordered* are not allowed inside *critical*

- Any directives legal inside a parallel region are also legal outside a parallel region in which case they are treated as part of a team of size one.

OpenMP: Contents

- OpenMP's constructs fall into 5 categories:
  - Parallel Regions
  - Worksharing
  - Data Environment
  - Synchronization
  - Runtime functions/environment variables

OpenMP: Library routines

- ## Lock routines

  – omp_init_lock(), omp_set_lock(), omp_unset_lock(), omp_test_lock()

- ## Runtime environment routines:

  – ### Modify/Check the number of threads

    – omp_set_num_threads(), omp_get_num_threads(), omp_get_thread_num(), omp_get_max_threads()

  – ### Turn on/off nesting and dynamic mode

    – omp_set_nested(), omp_set_dynamic(), omp_get_nested(), omp_get_dynamic()

  – ### Are we in a parallel region?

    – omp_in_parallel()

  – ### How many processors in the system?

    – omp_num_procs()

Lock: low-level synchronization functions

- **When to use lock**
  1) When the synchronization protocols required by a problem cannot be expressed with OpenMP's high-level synchronization constructs.
  2) When the parallel overhead incurred by OpenMP's high-level synchronization constructs is too large.

The simple lock routines are as follows:
- **omp_init_lock** routine initializes a simple lock.
- **omp_destroy_lock** routine uninitializes a simple lock.
- **omp_set_lock** routine waits until a simple lock is available, and then sets it.
- **omp_unset_lock** routine unsets a simple lock.
- **omp_test_lock** routine tests a simple lock, and sets it if it is available.

C/C++	Fortran
void omp_init_lock(omp_lock_t *lock);	integer (kind=omp_lock_kind) svar subroutine omp_init_lock(svar)

OpenMP: Library Routines

- **Protect resources with locks.**

```
   omp_lock_t lck;
   omp_init_lock(&lck);
#pragma omp parallel private (id, tmp)
{
   id = omp_get_thread_num();
   tmp = do_lots_of_work(id);
   omp_set_lock(&lck);
   printf("%d %d", id, tmp);
   omp_unset_lock(&lck);
}
```

OpenMP: Library Routines

- To fix the number of threads used in a program, first turn off dynamic mode and then set the number of threads.

```c
#include <omp.h>
void main()
{   omp_set_dynamic(0);
    omp_set_num_threads(4);
#pragma omp parallel
    {   int id=omp_get_thread_num();
        do_lots_of_stuff(id);   }
}
```

OpenMP excution model (nested parallel)
```fortran
program LIB_ENV
    use omp_lib
    implicit none
    integer :: nthreads
    logical :: dynamics, nnested
    integer :: myid
    write(*,*) "start"
    nthreads = omp_get_num_threads()
    dynamics = omp_get_dynamic()
    nnested = omp_get_nested()
    write(*,*) "nthreads, dynamics, nnested : ", nthreads, dynamics, nnested
    write(*,*) "before"
    !$omp parallel private(myid)
        !$omp master
            nthreads = omp_get_num_threads()
            dynamics = omp_get_dynamic()
            nnested = omp_get_nested()
            write(*,*) "nthreads, dynamics, nnested : ", nthreads, dynamics, nnested
        !$omp end master
        myid = omp_get_thread_num()
        write(*,*) "myid : ", myid
    !$omp end parallel
    write(*,*) "after"
end program
```

Example - pi

Example: Calculating π
- **Numerical integration**

$$\int_0^1 \frac{4}{1+x^2}\,dx = \pi$$

- **Discretization:**

$\Delta = 1/N$: `step = 1/NBIN`
$x_i = (i+0.5)\Delta \ (i = 0,\ldots,N\text{-}1)$

$$\sum_{i=0}^{N-1} \frac{4}{1+x_i^2}\Delta \cong \pi$$

```
#include <stdio.h>
#define NBIN 100000
void main() {
  int i; double step,x,sum=0.0,pi;
  step = 1.0/NBIN;
  for (i=0; i<NBIN; i++) {
    x = (i+0.5)*step;
    sum += 4.0/(1.0+x*x);}
  pi = sum*step;
  printf("PI = %f\n",pi);
}
```

OpenMP Program: `omp_pi_critical.c`

```c
#include <stdio.h>
#include <omp.h>
#define NBIN 100000
#define MAX_THREADS 8
void main() {
  double step,sum=0.0,pi;            // Shared variables
  step = 1.0/NBIN;
#pragma omp parallel
  {
    int nthreads,tid,i;              // Private (local) variables
    double x;
    nthreads = omp_get_num_threads();
    tid = omp_get_thread_num();
    for (i=tid; i<NBIN; i+=nthreads) {
      x = (i+0.5)*step;
#pragma omp critical
      sum += 4.0/(1.0+x*x);          // This has to be atomic
    }
  }
  pi = sum*step;
  printf("PI = %f\n",pi);
}
```

Shared variables

Private (local) variables

This has to be atomic

~syam/ces745/openmp/C/pi/source/pi-critical.c

Avoid Critical Section: `omp_pi.c`

```c
#include <stdio.h>
#include <omp.h>
#define NBIN 100000
#define MAX_THREADS 8
void main() {
  int nthreads,tid;
  double step,sum[MAX_THREADS]={0.0},pi=0.0;
  step = 1.0/NBIN;
#pragma omp parallel private(tid)
  {
    int i;
    double x;
    nthreads = omp_get_num_threads();
    tid = omp_get_thread_num();
    for (i=tid; i<NBIN; i+=nthreads) {
      x = (i+0.5)*step;
      sum[tid] += 4.0/(1.0+x*x);
    }
  }
  for(tid=0; tid<nthreads; tid++) pi += sum[tid]*step;
  printf("PI = %f\n",pi);
}
```

Array of partial sums for multi-threads

~syam/ces745/openmp/C/pi/source/pi-pregion.c

OpenMP PI Program:
Work sharing construct

```
#include <omp.h>
static long num_steps = 100000;        double step;
#define NUM_THREADS 2
void main ()
{         int i;        double x, pi, sum[NUM_THREADS];
          step = 1.0/(double) num_steps;
          omp_set_num_threads(NUM_THREADS);
#pragma omp parallel
{         double x;     int id;
          id = omp_get_thr ead_num();        sum[id] = 0;
#pragma omp for
          for(i=0;i< num_steps; i++){
                  x = (i+0.5)*step;
                  sum[id] += 4.0/(1.0+x*x);
          }
}         for(i=0, pi=0.0;i<NUM_THREADS;i++)pi += sum[i] * step;
}
```

OpenMP PI Program :
Parallel for with a reduction

```c
#include <omp.h>
static long num_steps = 100000;        double step;
#define NUM_THREADS 2
void main ()
{        int i;    double x, pi, sum = 0.0;
         step = 1.0/(double) num_steps;
         omp_set_num_threads(NUM_THREADS);
#pragma omp parallel for reduction(+:sum) private(x)
         for (i=1;i<= num_steps; i++){
                 x = (i-0.5)*step;
                 sum = sum + 4.0/(1.0+x*x);
         }
         pi = step * sum;
}
```

OpenMP adds 2 to 4
lines of code

```c
#include <omp.h>          /* OpenMP header file*/
#define NUM_STEPS 100000000

int main(int argc, char *argv[]) {
    int i;
    double x, pi;
    double sum = 0.0;
    double step = 1.0/(double) NUM_STEPS;
    int nthreads;
    /* do computation -- using all available threads */
    #pragma omp parallel
    {
        #pragma omp master
        {
            nthreads = omp_get_num_threads();
        }
        #pragma omp for private(x) reduction(+:sum) schedule(runtime)
        for (i=0; i < NUM_STEPS; ++i) {
            x = (i+0.5)*step;
            sum = sum + 4.0/(1.0+x*x);
        }
        #pragma omp master
        {
            pi = step * sum;
        }
    }
    /* print results */
    printf("parallel program results with %d threads:\n", nthreads);
    printf("pi = %g  (%17.15f)\n",pi, pi);
    return EXIT_SUCCESS;
}
```

pi-parallel_timing.c

OpenMP: Performance Issues

Key Factors that impact performance

Run on orca: /home/syam/ces745/openmp/jacobi/c

[syam@orc132:~/ces745/openmp/jacobi/c] ./jacobi_omp2 < input.large
Input n,m - grid dimension in x,y direction :
 Input alpha - Helmholts constant :
Input relax - Successive over-relaxation parameter:
 Input tol - error tolerance for iterrative solver:
Input mits - Maximum iterations for solver:
 -> 5000, 5000, 0.8, 1, 1e-07, 1000
Total Number of Iteratuons 2
Residual   0.000000000038394
 elapsed time :   0.135430
 MFlops   :   -12386.2
Solution Error : 0.000106635

Load Balance

Example: Sparse matrix

Data is not uniformly distributed, one thread will get more points than another.

Solution: Dynamic schedule

If load balancing is the most important issue to performance, perhaps we should use dynamic scheduling.

However, dynamic scheduling costs more than static:

1) more synchronization cost: each thread needs to go to the runtime library after each iteration and ask for another iteration to execute.

Increasing the chunk size can reduce the synchronization overheads, but it will worsen the load balance.

2) data locality (distance in the cache, etc)

Load Balance: continue

Example: dense triangle matrix-scaling

```
for (i=0; i < n; i++){
    for (j=i; j<n; j++){
        a[i][j] = c* a[i][j]
    }
}
```

Each iteration has a different amount of work, but the amount of work varies regularly

Each successive iteration has a linearly decreasing amount of work

Solution: static schedule with a relatively small chunk size

Locality

The Memory Hierarchy

- Most parallel systems are built from CPUs with a memory hierarchy
  - Registers
  - Primary cache
  - Secondary cache
  - Local memory
  - Remote memory - access through the interconnection network
- As you move down this list, the time to retrieve data increases by about an order of magnitude for each step.
- Therefore:
  - Make efficient use of local memory (caches)
  - Minimize remote memory references

Performance Tuning - Cache Locality

- The basic rule for efficient use of local memory (caches):

  ## Use a memory stride of one

- This means array elements are accessed in the same order they are stored in memory.

- Fortran: "Column-major" order
  - Want the leftmost index in a multi-dimensional array varying most rapidly in a loop

- C: "Row-major" order
  - Want rightmost index in a multi-dimensional array varying most rapidly in a loop

- Interchange nested loops if necessary (and possible!) to achieve the preferred order.

Column major arrays vs. row major arrays

A two dimentional array like A[3][3]:

A11 A12 A13
A21 A22 A23
A31 A32 A33

Main memory is just like a big 1D array with indices from 0x0 to 0Xffffff
This is **FORTRAN**'s column major order in memory:
A11 A21 A31 A12 A22 A32 A13 A23 A33

This is **C/C++**'s row major order in memory:
A11 A12 A13 A21 A22 A23 A31 A32 A33

Which of the following is faster in C?

```
for (i=0; i < 10000; i++)
  for (j=0; j < 10000; j++)
    sum += a[i][j];
```

```
for (j=0; j < 10000; j++)
  for (i=0; i < 10000; i++)
    sum += a[i][j];
```
